### DATA MODEL

A data model within a Database Management System (DBMS) serves as an abstract representation of how data gets structured and organized within a database.

It outlines the logical arrangement of data and the connections between various data components.

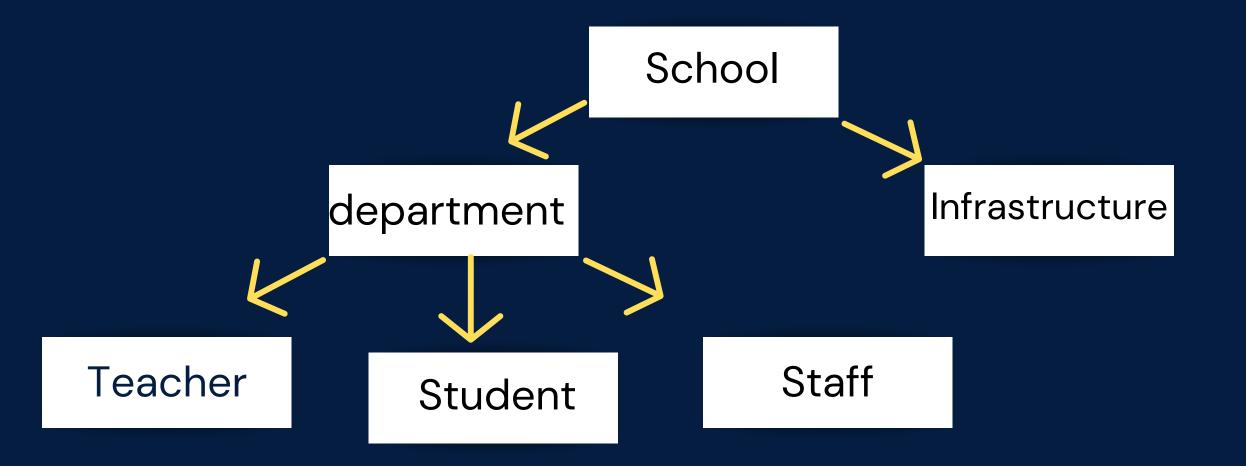

Data models play a crucial role in comprehending and shaping databases, acting as a vital link between real-world entities and the actual storage of data within the database.

# DATA MODEL

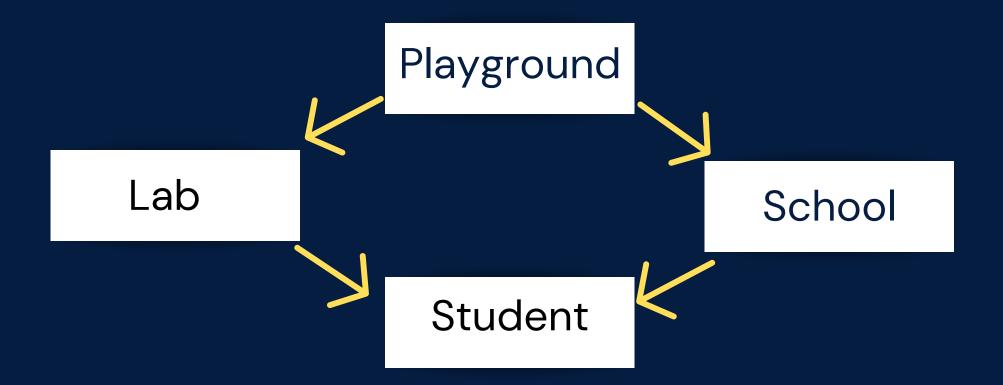

#### Types of Data Model

- Hierarchical Data Model
- Network Data Model
- Relational Data Model
- Entity-Relationship Model (ER Model)
- Object-Oriented Data Model
- NoSQL Data Models

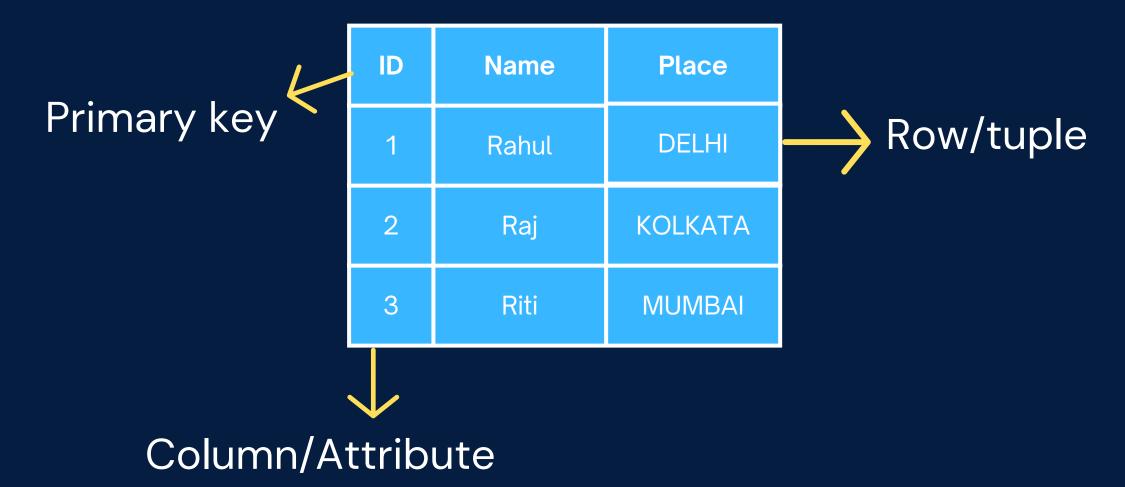

• Hierarchical Data Model: This model portrays data in a manner resembling a tree structure, where each record maintains a parent-child relationship. Its primary application lies in older database systems.

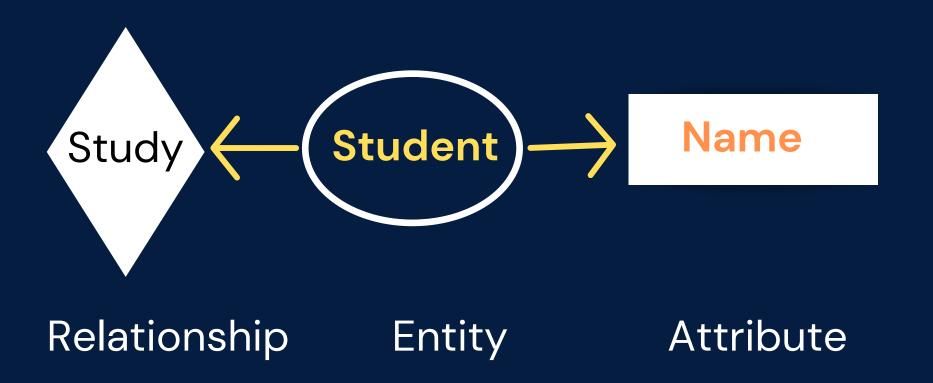

• Network Data Model: This model shares similarities with the hierarchical approach, permitting records to hold multiple parent-child relationships. It adopts a structure akin to a graph, offering more flexibility compared to the hierarchical model.

• Relational Data Model: Organizing data into tables (known as relations) consisting of rows and columns characterizes the relational model. It stands as the most prevalent data model, rooted in the principles of set theory, and relies on Structured Query Language (SQL) for data manipulation.

• Entity-Relationship Model (ER Model): Utilized for crafting relational databases, the ER model represents data through entities (objects), attributes (entity properties), and relationships connecting these entities.

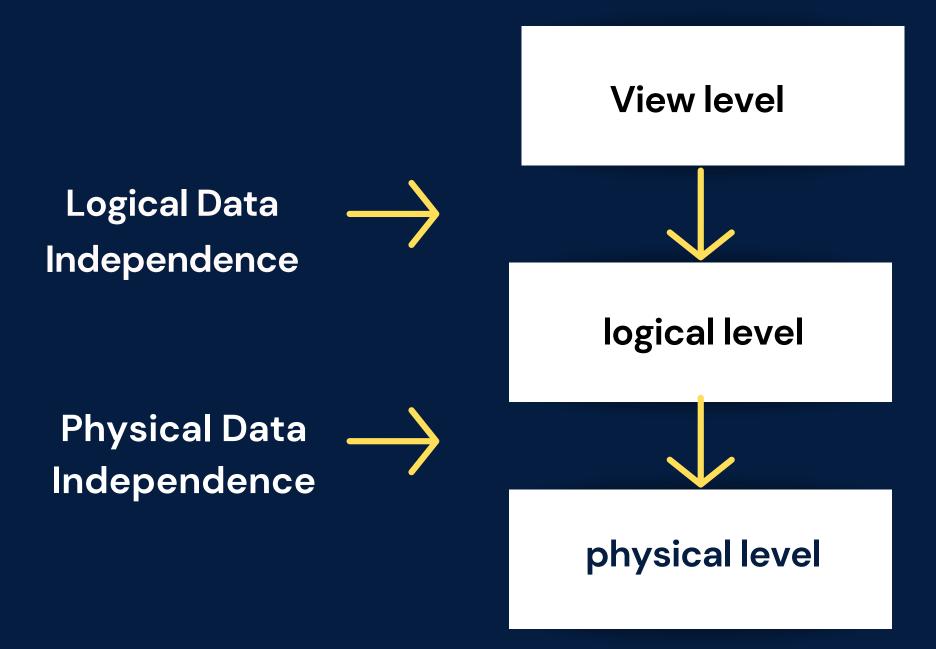

- <u>Object-Oriented Data Model:</u> Extending the principles of object-oriented programming into the database domain, this model depicts data as objects complete with attributes and methods, fostering support for inheritance and encapsulation.
- NoSQL Data Models: NoSQL databases encompass a diverse array of data models, such as document-oriented (e.g., MongoDB), key-value (e.g., Redis), column-family (e.g., Cassandra), and graph (e.g., Neo4j). These models are designed to offer scalability and flexibility when handling extensive volumes of unstructured or semi-structured data.

## DATA INDEPENDENCE

Data independence is a fundamental concept within database design and management, emphasizing the distinction between the logical and physical dimensions of data storage and administration in a database management system (DBMS). This principle yields various benefits, such as enhanced flexibility, heightened security, and simplified maintenance.

# DATA INDEPENDENCE

There are three levels of Abstraction

## **ESSENTIAL COMPONENTS OF TABLES**

<u>Row/Tuple</u> – Rows, also known as records or tuples, represent individual entries or instances of data within the table.

Cardinality - No of rows in a table

Column/Attribute - Columns represent the attributes of the data being stored and are named to describe the information they hold (e.g., "ID," "Name," "Age").

Degree - No of Columns in a ta in a tableble

# ESSENTIAL COMPONENTS OF TABLES

Rows/	9
Tuple	

7 Primary			key
ID	Name	Place	U
1	Rahul	DELHI	
2	Raj	KOLKATA	
3	Riti	MUMBAI	

Colemns/ Attributes

# **ESSENTIAL COMPONENTS OF TABLES**

<u>Constraints</u> - Constraints define rules or conditions that must be satisfied by the data in the table.

Common constraints include uniqueness, nullability, default values, etc.

- Unique constraint: Ensures values in a column are unique across the table.
- Not null constraint: Ensures a column cannot have a null value.
- Check constraint: Enforces a condition to be true for each row.
- Default constraint: Provides a default value for a column if no value is specified.

**Keys** - A primary key is a unique identifier for each record in the table. It ensures that each row can be uniquely identified and accessed within the table.

A foreign key is a field in a table that refers to the primary key of another table. It establishes relationships between tables.

# VIEWS IN DBMS

View is a virtual table that is derived from one or more underlying tables. This means that it doesn't physically store data but rather provides a logical representation of data.

Customer DB

ID.	NAME	phn	Address	Pin	Age
1	Raj	456	blr	123	18
2	Ravi	123	delhi	124	21
3	Ram	789	hyd	345	22

Keys in DBMS make sure of data integrity, uniqueness, and the quick retrieval of information. Key is a attribute in table

#### Types of keys:

- Candidate Key
- Primary Key
- Foreign Key
- Super Key

<u>Candidate Key</u>: A candidate key refers to a group of attributes capable of uniquely identifying a record within a table. Among these, one is selected to serve as the primary key.

Ex- For student possible attributes for candidate key could be

#### Student ID, Roll no , Aadhar Card

Age	Name	Hometown
20	Rahul	KOLKATA
21	Raj	KOLKATA
20	Riti	DELHI

<u>Primary Key</u>: A primary key is a key which uniquely identifies each record in a table. It ensures that each tuple or record can be uniquely identified within the table. It is always <u>Unique+ Not null</u>

ID	Name	Hometown
123	Rahul	KOLKATA
245	Raj	KOLKATA
434	Riti	DELHI

Foreign Key: A foreign key is a field in a table that refers to the primary key in another table. It establishes a relationship between two tables.

#### Student

Primary key

(Base/referenced table)

Roll no	Name	Hometown
1	Rahul	KOLKATA
2	Raj	KOLKATA
3	Riti	DELHI

#### Subject

(referencing table)

Roll no	Name	subject
1	Rahul	Maths
2	Raj	SST
3	Riti	Science

Foreign key

Referenced table - Table having primary key (pk) Referencing table- Table having foreign key(fk)

#### Student

(Base/referenced table)

Roll no	Name	Hometown
1	Rahul	KOLKATA
2	Raj	KOLKATA
3	Riti	DELHI

Primary key

#### Subject

(referencing table)

Roll no	subject id	subject
1	s1	Maths
2	s2	SST
3	s3	Science

Foreign key

#### Referential Integrity in Foreign key

Referential integrity is an important concept in foreign key. We always say foreign key maintains referential integrity.

Referential integrity ensures that the relationships between tables remain accurate, consistent, and meaningful within a relational database.

#### Referential Integrity in Foreign key

Now consider there are two tables one is refrencing and other is refrenced table .

Lets see how some operations like insert, update and delete works here.

### Refrential Integrity in Foreign key

• Insertion in Referenced/base table

No violation

### Refrential Integrity in Foreign key

• Deletion in Referenced/base table May cause violation if the coressponding data is present in refrencing table.

#### Refrential Integrity in Foreign key

If a record in referenced table is deleted or updated, the corresponding records in the referencing table should be deleted or updated to maintain the integrity of the relationship.

We using action like "CASCADE DELETE" for the same. Also we can set null for the values deleted.

#### Refrential Integrity in Foreign key

• Updation in Referenced/base table

May cause violation if the coressponding data is present in refrencing table. We can using action like "CASCADE UPDATE".

### Refrential Integrity in Foreign key

• Insertion in Referencing table

May cause violation

### Refrential Integrity in Foreign key

• Deletion in Referencing table

No violation

#### Refrential Integrity in Foreign key

• Updation in Referencing table

No issues untill we are updating foreign key attribute Voilation would be caused on updating

Integrity constraints help to ensure that data remains reliable and meaningful throughout its lifecycle.

Types of Integrity Constraint:

- Domain Integrity Constraint
- Entity Integrity Constraint
- Referential Integrity Constraint
- Key Constraint
- Check Constraint
- Null Constraint
- Unique Constraint
- Default Constraint

### **Domain Integrity Constraint**

It ensures the validity and appropriateness of data values (i.e valid data types, ranges, and formats for columns) within a specific column or attribute of a table.

Ex-> Check for date column so that it contains valid date values

### **Entity Integrity Constraint**

It ensures that each row/record in a table is uniquely identified by a primary key.

It also helps in preventing duplicate or null values in the primary key.

### Referential Integrity Constraint

It ensures that values in a foreign key column match with the values in the corresponding primary key column in another table.

### **Key Constraint**

It ensures uniqueness for the primary key.

#### **Check Constraint**

It checks for a condition that each row in a table must satisfy.

If the condition is not met, the insertion or update of the row is rejected.

#### **Null Constraint**

It determines whether a column in a table can have null (i.e., missing or unknown) values or not.

### **Unique Constraint**

It ensures that values in a specified column or combination of columns are unique across a table.

This constraint prevents duplicate values from being inserted into the specified column(s), maintaining data consistency and integrity.

### **Default Constraint**

It ensures a default value for a column, which is used if no other value is provided

### **SUPER KEY IN DBMS**

It is a set of one or more attributes (columns) that can uniquely identify a tuple (a row) in a relation (table).

Superset of any candidate key.

A super key becomes a candidate key if it is minimal (i.e. no proper subset of it can uniquely identify a tuple).

Things/Object

Properties of entity

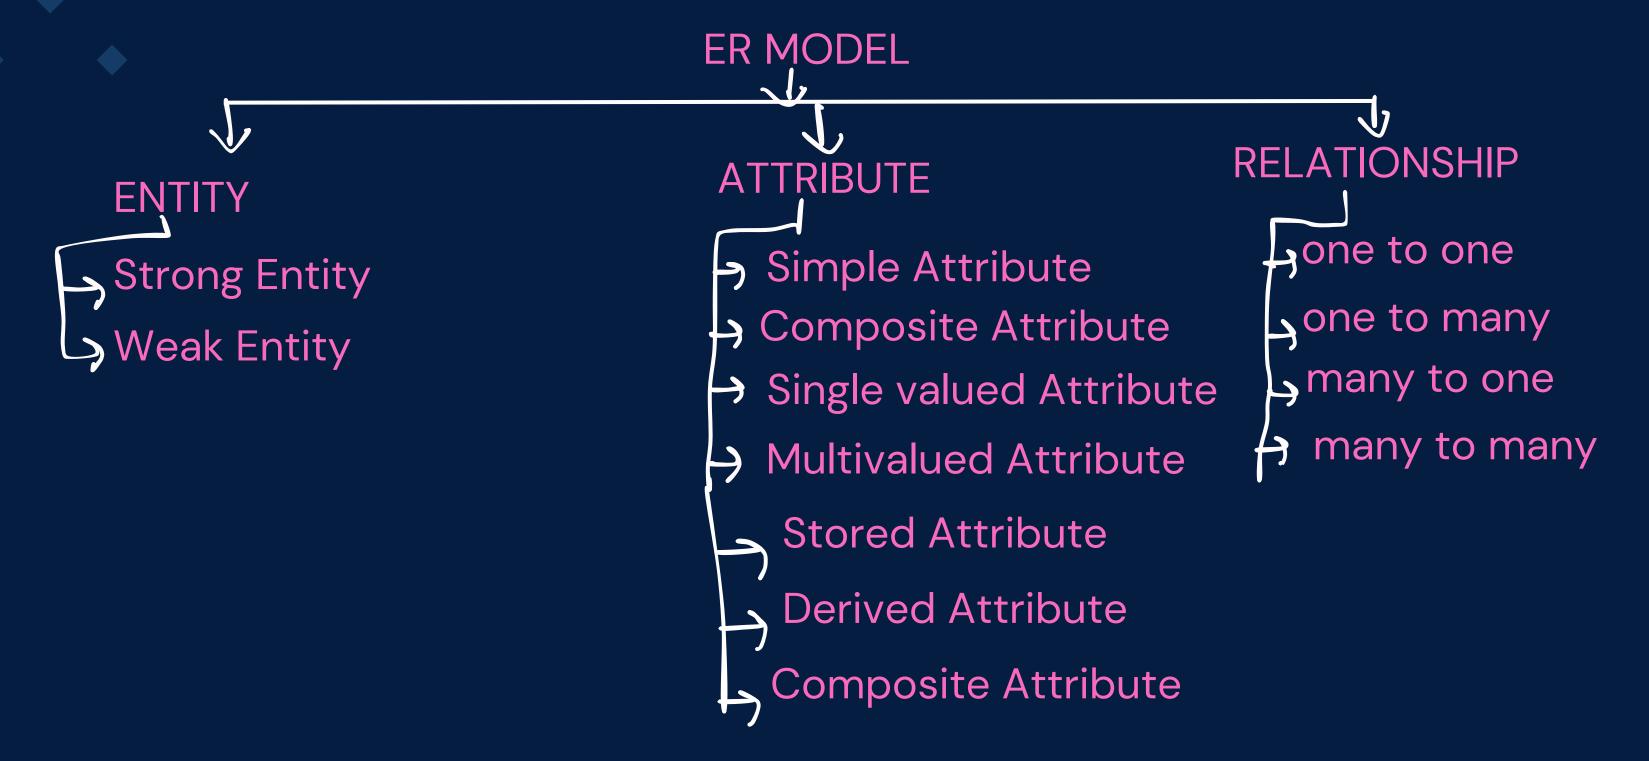

association among entities

Ex-person

Ex-name,age

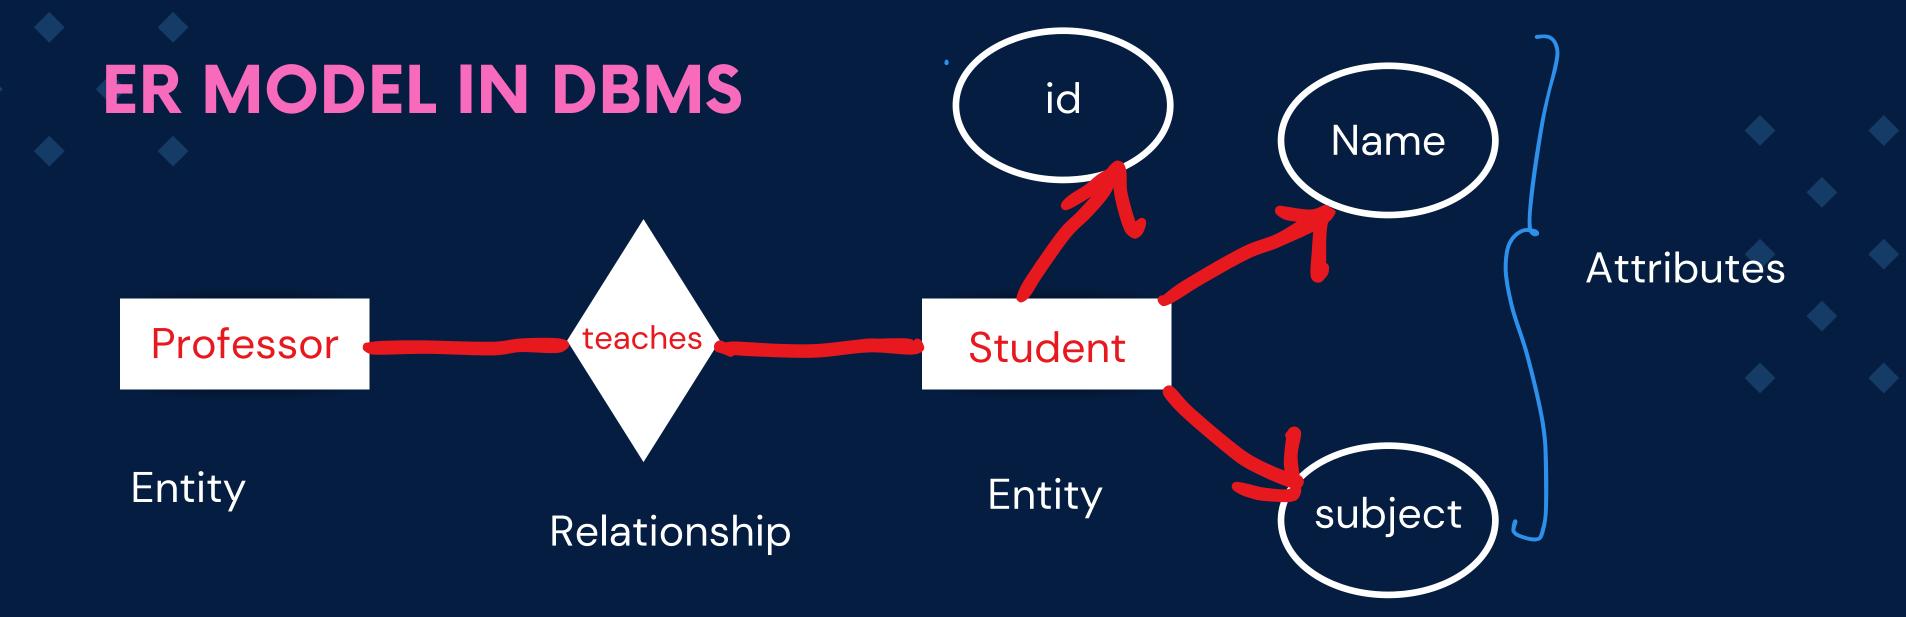

Ex-Works for

- The Entity-Relationship (ER) model stands as a prevalent conceptual modeling approach within the realm of database design.
- Its primary role is to offer a visual representation of a database's architecture by illustrating the entities, their respective attributes, and the interconnections between them.
- In the process of database design, the ER model holds significant importance, aiding in the development of an efficient and systematically structured database schema.

### Symbols used in ER Model

Figures	Symbols	For what
Rectangle		Entity
Ellipse		Attribute
Diamond		Relationship
Line		Attribute to entity relationship
Double ellipse		Multivalued attributes
Double rectangle		Weak Entity

#### • Entity

An entity is something from the real world, like a person, place, event, or idea. Each entity has specific features or traits that describe it.

#### **Types of Entity**

**Strong Entity**: A strong entity is an entity that has its own unique identifier (primary key) and is not dependent on any other entity for its existence within the database. Strong entities stand alone and have their own set of attributes.

Ex-Person

Weak Entity: A weak entity is an entity that doesn't have a primary key of its own. It relies on a related strong entity (known as the "owner" entity) for its identity. The weak entity's existence is defined by being related to the owner entity. ex- dependent

#### **Attribute**

Attributes represent properties or characteristics of an entity or relationship.

They provide information about the entities and relationships in the database.

#### **Types of Attributes**

#### Simple Attribute

A simple attribute is atomic and cannot be divided any further.

Ex- First Name

#### **Types of Attributes**

#### **Composite Attribute**

A composite attribute is made up of several smaller parts, where each part represents a piece of the whole attribute. In simpler terms it is composed of attributes which can be divided further.

Ex- Name(First Name, lastName)

#### **Types of Attributes**

#### Single Valued Attribute

A single-value attribute is an attribute that holds a single value for each entity

Ex- Age

#### **Types of Attributes**

#### **Multivalued Attribute**

A multi-valued attribute in a database is an attribute that can hold multiple values for a single entity.

Ex- Address (permanent, residential)

#### **Types of Attributes**

#### **Stored Attribute**

Attribute that is stored as a part of a database record.

Ex- Date of birth

#### **Types of Attributes**

#### **Derived Attribute**

A derived attribute is derived from other attributes within the database.

Ex- Age derived from dob

#### **Types of Attributes**

#### **Complex Attribute**

A complex attribute is an attribute that is made up of multiple smaller attributes

Ex- Name(Composite) FirstName (Simple attribute) lastName

#### Relationship in ER Model

Relationship in ER MODEL is the connection between entities (tables) based on related data.

**Types of Relationship** 

**Strong Relationship** 

Weak Relationship

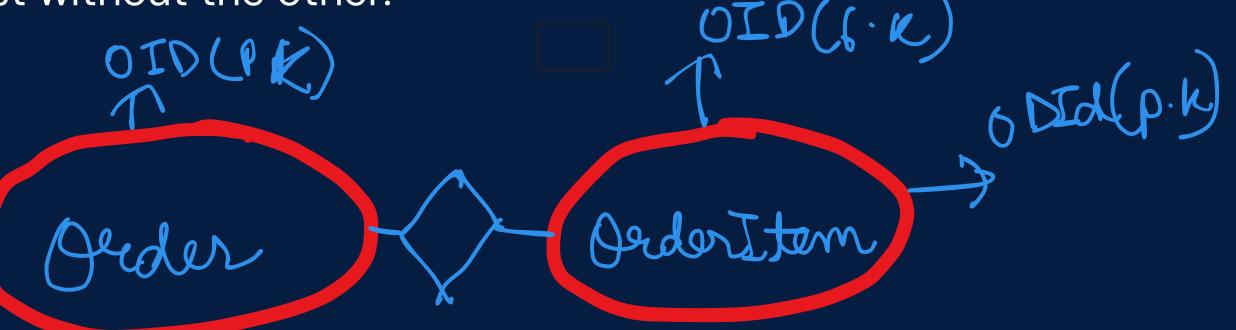

#### **Strong Relationship**

A strong relationship exists when two entities are highly dependent on each other, and one entity cannot exist without the other.

#### Weak Relationship

A weak relationship, on the other hand, exists when two entities are related, but one entity can exist without the other.

Ех-

### Degree in DBMS

A degree in dbms refers to the number of attributes / columns that a relation/table has.

# Types of Degree

Degree	Name	Defination
1	Unary Degree	A relation with a single attribute
2	Binary Degree	A relation with two attributes
3	Ternary Degree	A relation with three attributes
n	n-ary Degree	A relation with more than three attributes n>3

Null value: In databases, a null value can occur for various reasons

Not Needed Information: Sometimes, some details are asked, but they don't apply to everyone. For instance, asking for a "Spouse Name" from someone who isn't married.

Don't Know the Answer: Every now and then, we're asked a question, but we don't have an answer yet.

Forgot to Fill In: Like when you're filling out a form, and you accidentally miss putting in some important information.

### Types of relationship in dbms (Based on degree)

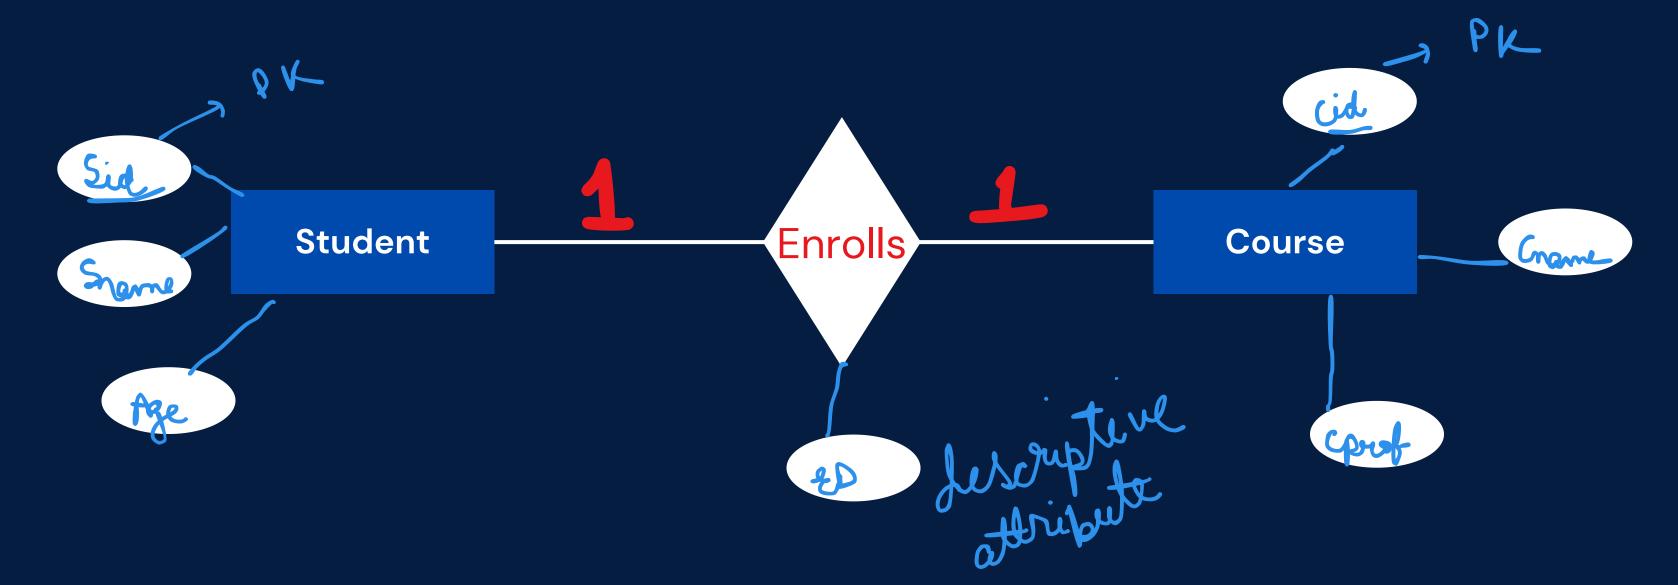

There are 4 types of relationship:

- one to one (1-1)
- one to many (1-N)
- many to one (N-1)
- many to many (N-N)

#### Types of Relationship(Cardinality)

#### 1 to 1 Relationship (1:1)

A complex attribute is an attribute that is made up of multiple smaller attributes

Types of Relationship(Cardinality)

1 to 1 Relationship(1:1)

#### Participation Constraints

Participation Constraints in an ER model define whether every entity in one group must be connected with at least one entity in another group or if the connection is optional.

#### Types of Participation Constraints

#### Total Participation (Mandatory)

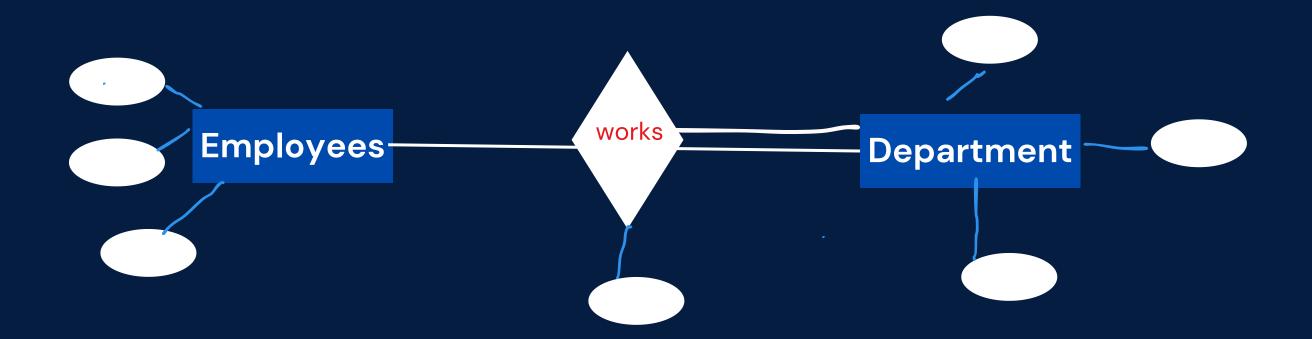

In a total participation constraint, each entity in a participation set must be associated with at least one entity in the related entity set.

#### **Types of Participation Constraints**

#### Partial Participation(Optional)

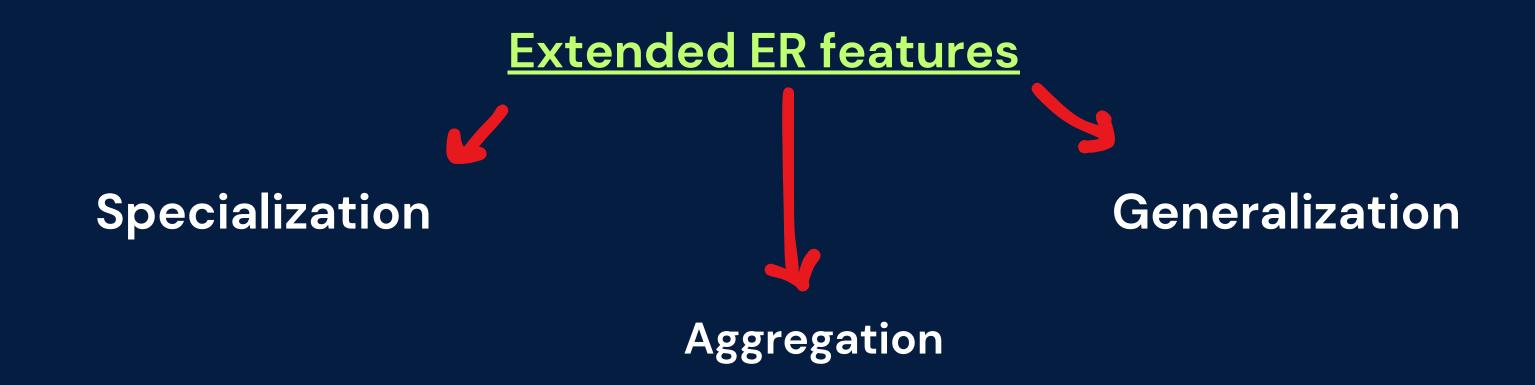

In a partial participation constraint, entities in the participating entity set may or may not be associated with entities in the related entity set.

#### **Extended ER features**

Why do we need?

We design ER model for relationship betwn entities In real-world the data may exhibit some hierarchical relationships, and the EER model provides mechanisms to represent these relationships accurately which helps in code reusabilitilty, ensuring data integrity and consistency and lower the complexity.

#### **Extended ER features**

#### **Specialization**

Specialization in the ER model is like categorizing entities based on common features.

A "Supertype" groups entities with shared attributes and relationships, while "Subtypes" have their own unique attributes and relationships. It's a way to organize data efficiently. It is a **Top-Down approach**.

We have is-a relationship between superclass and subclass.

#### **Extended ER features**

#### Generalization

Generalization is like finding things that are alike and putting them into a big group to represent what they have in common. It helps make things simpler and organized.

It is a Bottom-Up approach.

We have is-a relationship between subclass and superclass.

#### **Extended ER features**

Attribute Inheritance
Participation

#### **Extended ER features**

#### **Aggregation**

Aggregation is like stacking things on top of each other to create a structure. It is used to create a hierarchical structure in data modeling, showing how a higher–level entity is composed of lower–level entities.

**Abstraction** is employed to view relationships from a more general perspective, focusing on a higher-level entity.

#### Steps to draw an ER model

- 1. Recognize entities.
- 2. Specify entity characteristics/attributes.
- 3. Discover connections/relationships(also contraints like mapping/participation)
- 4. Define the connection type (how entities connect)/cardinality.
- 5. Construct an ERD (Entity-Relationship Diagram).
- 6. Annotate relationships and attributes.
- 7. Review and refine the model.
- 8. Document the model.
- 9. Validate with stakeholders.
- 10. Implement the database schema.

#### ER Model of Instagram

Lets start with what is instagram?

Instagram is a social media platform that allows users to share photos and videos.

#### **ER Model of Instagram**

Now what all things we can do on instagram?

- Create our profile
- Add profile picture and details
- Connect with friends
- Upload a post
- Like and comment on post
- Share stories
   and much more

#### **ER Model of Instagram**

Lets start with all the steps needs to draw an ER diagram.

#### Step-1: Recognize entities sets

#### Entities

- userProfile
- userFriends
- userPost
- userLogin

userLikes

#### **ER Model of Instagram**

Step-2: Specify entity characteristics/attributes

Attributes

1. userProfile (user ID, username, email, profile pic)

user ID- primary key userName- composite attribute email - single valued attribute profile pic - single valued attribute dob- stored attribute age- derived attribute

#### **ER Model of Instagram**

Step-2: Specify entity characteristics/attributes

Attributes

2. userFriends (followerID, followerName, userID)

followerID- primary key followerName - single valued attribute userID - single valued attribute

#### **ER Model of Instagram**

Step-2: Specify entity characteristics/attributes

Attributes

3. userPost (post ID, caption, image, video, likesCount, timestamp)

post ID- primary key
caption - single valued attribute
image - multi valued attribute
video - multi valued attribute
likesCount - single valued attribute
timestamp - single valued attribute

#### ER Model of Instagram

Step-2: Specify entity characteristics/attributes

Attributes

4. userLogin (login ID,loginUserName,loginPassword)

login ID- primary key loginUserName - single valued attribute loginPassword - multi valued attribute

#### ER Model of Instagram

Step-2: Specify entity characteristics/attributes

Attributes

4. userLikes (postID, userID)

postID- primary key userID - single valued attribute

#### **ER Model of Instagram**

Step-2: Discover connections/relationships(also contraints like mapping/participation)

1.userProfile have userFriends (n:n)

- 2. userProfile have userPost (1:n) userPost will always be associated to a userProfile therefore total participation
- 3. userProfile has userLogin (1:1)
- 4. userProfile has userLikes (1:n) userLikes will always be associated to a userProfile therefore total participation

#### ER Model of Instagram

Step-2: Discover connections/relationships(also contraints like mapping/participation)

- 5. userFriends have userPost (1:n) userPost will always be associated to a userProfile therefore total participation
- 6. userFriends has userLogin (1:1)
- 7. userFriends has userLikes (1:n) userLikes will always be associated to a userProfile therefore total participation

#### RELATIONAL MODEL

It is a way of organizing data in tables.

Some terms used in relational model

- 1. Table Relation
- 2. Row Tuple
- 3. Column Attribute
- 4. Record Each row in a table
- 5. Domain The type of value an attribute can hold
- 6. Degree No. of columns in a relation
- 7. Cardinality No of tuples

### RELATIONAL MODEL

Relational model is all about:

- Data being organized into tables
- Establishing Relationships between tables using Foreign key
- Maintaining data Integrity
- A flexible and efficient way to store(SQL) and retrieve data

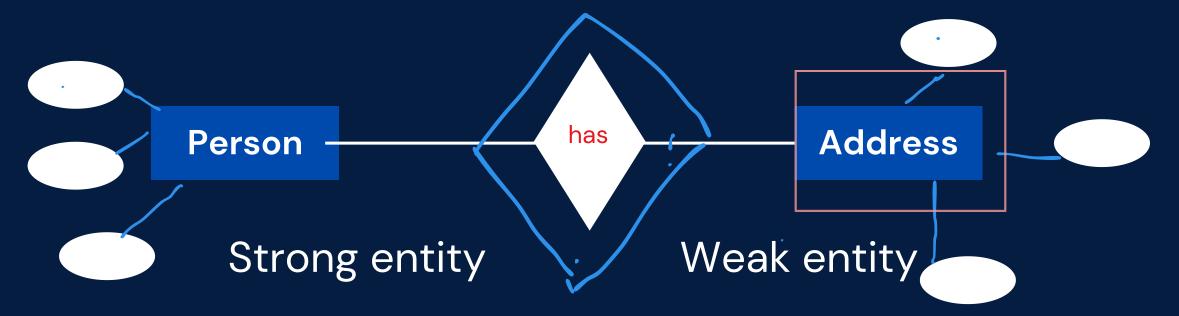

### RELATIONAL MODEL

In relational model we take care of different things like:

- 1. Maintaining integrity constraints like domain, entity, referential integrity.
- 2. The values to be atomic i.e can't be divided further.
- 3. Each row must be unique, here keys comes into picture i.e candiate, super, primary etc

Converting an Entity-Relationship (ER) model to a relational model involves several steps:

Step 1: Identify the entities - List down all the entities like strong and weak.

Person (id, name, age) -> id (p.k) Address (id, flatno, street, city)->id+flatno (p.k), id (f.k)

Step 2: **Identify the attributes** - For each entity, identify its attributes which becomes a column in the table.

Multivalued attribute

Composite attribute

Step 3: **Key selection** - Choose the primary key for each table, for some it can be in form of composite key (Weak entity)

# Step 4: If entities have relationship break it down and the reduce the tables if possible.

- 1. 1-1 Relationship : 2 tables , P.K can lie on any side
- 2. 1-Many Relationship: 2 tables, P.K can lie on many side
- 3. Many -1 relationship: 2 tables, P.K can lie on many side
- 4. Many-Many relationship: 3 tables, P.K lie in the relation table having pk from both the table acting as fk

Step 3: Key selection - Choose the primary key for each table, for some it can be in form of composite key (Weak entity)
